An Approximate Auction*

Jim Ingebretsen Carlson†

Abstract

This paper presents an auction procedure which is of particular interest when short execution times are of importance. It is based on a method for approximating the bidders’ preferences over two types of items when complementarity between the two may exist. In particular, linear approximations of the bidders’ indifference curves are made. The resulting approximated preference relation is shown to be complete and transitive at any given price vector. It is shown that an approximated Walrasian equilibrium always exists if the approximated preferences of the bidders comply with the gross substitutes condition. Said condition also ensures that the set of approximated equilibrium prices forms a complete lattice. A process is proposed which is shown to always reach the smallest approximated Walrasian price vector.

Keywords: Approximate auction; one-round auction; non-quasi-linear preferences; approximated preferences.

JEL classification: D44.

1 Introduction

Auctions are extensively used as a way to determine who gets to buy what and to which price. Governments commonly use auctions as a mean to sell treasury bills and companies that are to be privatized. The growth of e-commerce highlights the common use of auctions. At sites such as eBay and eBid it is possible to find a wide range of items being auctioned, the latter having over 4 million daily listings1. A single auction may be of great economic importance. The auction for telecom licenses, which was conducted by the British government during two months in 2000, serves as such an example as it generated 34 billion dollars (Binmore and Klemperer, 2002). For reasons such as these, the study of auctions is important.

It is not uncommon for a seller to simultaneously auction multiple items. Spectrum licenses are often divided into smaller geographical areas rather than one countrywide license and a company can be sold as several divisions rather than one entity. In recent years, the literature on multi-item auctions and in particular combinatorial auctions has grown substantially. In a unit-demand setting, Demange et al. (1986) propose a multi-item auction, which is Pareto efficient and strategy-proof. Key to their result is to find the unique minimal Walrasian equilibrium price vector, its existence being guaranteed by the lattice structure of equilibrium prices (Demange and Gale, 1985; Shapley and Shubik, 1971), and to allocate the items in accordance with this price. Allowing bidders to demand multiple units of items, the problem becomes more complex. For homogeneous items, Ausubel (2004) presents an ascending-bid auction, which is efficient and where the outcome of the auction coincides with the outcome of the Vickrey auction. Extending to heterogeneous items, Gul and Stacchetti (2000) design a generalized version of Demange et al. (1986)'s auction, which also terminates at the unique minimal Walrasian equilibrium price vector. In their setting, the existence of a Walrasian equilibrium is guaranteed when bidders have gross substitute preferences. The gross substitutes condition was introduced by Kelso and Crawford (1982) and is utilized by Ausubel (2006), who suggests a multi-item auction that reaches the Vickrey-Clarkes-Groves outcome and therefore is incentive compatible. By limiting the class of preferences, Bikhchandani et al. (2011) propose a dynamic process with the novelty that it is computable in pseudo polynomial- or polynomial time. Sun and Yang (2006, 2009) introduce the gross substitutes and complements condition, which allows for some complementarity in the bidders’ preferences. The authors show that this condition is sufficient for the existence of competitive equilibrium and propose two auction processes that always finds an equilibrium price vector. Ausubel and Milgrom (2002) suggest an ascending-bid proxy auction: Each bidder reports a valuation for each package and then commits to bid straightforwardly according to these reports. When bidders have quasi-linear preferences in money and goods are substitutes, the outcome of the proxy auction coincides with the Vickrey auction and sincere bidding is a Nash equilibrium. By allowing prices to differ across packages and bidders, authors such as de Vries et al. (2007) and Mishra and Parkes (2007) have proposed auction processes that reach the VCG outcome for general valuations.

A possible problem with many auction formats is that execution times can be long. The auction for British telecom licenses, in the year 2000, serves as such an example as it took two months to conduct. A reason for long execution times may be that the prices of some items are either only increased or only decreased in many auction processes. This may result in a time-consuming process as the starting prices have to be set far below or far above the final prices to make sure that the desired final prices are actually reached. In some cases, however, short execution times of auctions are very important. This can be

---

2Auction processes converging to the unique minimal equilibrium price vector is common in the literature, see e.g. Andersson et al. (2013); Andersson and Erlanson (2013); Mishra and Talman (2010); Sankaran (1994).

3For auction processes that may be both ascending and descending see e.g. Andersson and Erlanson (2013); Ausubel (2006); Erlanson (2014); Grigorieva et al. (2007).
exemplified by the Product-mix auction designed to help the Bank of England during the bank run in the autumn of 2007. Due to the outbreak of the financial crisis, the Bank of England wished to allocate loans to commercial banks in a very rapid fashion. Klemperer (2010) proposed a single-round auction for allocating two different types of loans to the banks. The idea was that bidders submitted a number of bids consisting of two prices (interest rates), one for each type of loan, and a quantity (same for both loans), which served as an approximation of the bidders’ demand. Based on the supplied quantities of the two loans, prices were determined and the bidders were awarded the loans which gave them the highest, non-negative, profit. In this way, the central bank allocated the loans using a one-round auction. This paper relates to Klemperer’s work as a one-round auction is proposed.

Common to the papers mentioned earlier is the assumption that bidders have quasi-linear preferences in money. Such an assumption may be restrictive as it implies that bidders neither exhibit risk-aversion, experience wealth effects, nor face financing- or budget constraints. If bidders’ preferences are in fact non-linear in money we may, by taking this into account, improve the outcome of an auction. This paper will allow for non-linearity in the bidders’ preferences. Optimal auctions, where bidders exhibit risk-aversion, have been studied by Maskin and Riley (1984) and Matthews (1987). Morimoto and Serizawa (2014) analyze allocation rules for multiple indivisible items, allowing bidders to have non-linear preferences in money and unit-demand. Ausubel and Milgrom (2002) also propose a generalized proxy auction, where the seller and the bidders have non-linear but strict preferences over all offers made in the bidding process. This auction is embedded in the matching with contracts model by Hatfield and Milgrom (2005).

Thus far, two problems have been identified: Auctions may take a long time to conduct and bidders may not have quasi-linear preferences in money. This paper will aim at solving these two problems. In particular, this paper proposes a way to conduct a one-round combinatorial auction when the participating bidders may have non-linear preferences in money. The way this is done is by having each bidder report two vectors of prices, which will be used to construct an approximated preference relation for each bidder. The proposed one-round auction process is then shown to be efficient with respect to these approximations. More specifically, the auctioneer wishes to sell multiple copies of two types of items and the bidders are interested in acquiring a package, which consists of at most one item of each type. The approximation procedure starts with each bidder reporting two vectors of prices, where each vector consists of one price for each package. The prices reported in each vector should represent prices which makes the bidder indifferent between the packages. It is required that one vector is strictly greater than the other. Based on this information, all prices which make the bidder indifferent between any two packages are approximated in a linear fashion. In other words, linear approximations of the bidders’ indifference curves are made. In this way, the approximated indifference curves form an approximation of a bidder’s true preference relation.

As suggested above, linear approximations of bidders preferences are not uncommon. Andersson and Andersson (2009) investigate the error of the outcome that a quasi-linear approximation of bidders’ preferences might give rise to in a house allocation problem.
with money. Their results suggest that quasi-linear approximations of the bidders’ true preferences work fairly well. The quasi-linear preferences are contained in the class of preferences corresponding to the approximation procedure of this paper. In particular, if a bidder has quasi-linear preferences in money and reports truthfully, the approximated preference relation will coincide with the true preference relation of the bidder.

It is shown that the approximated preference relation of each bidder is complete and transitive at any price vector. Given the approximated preference relations of the bidders, it is of interest to know whether it is always possible to find an equilibrium assignment. In addition to theoretical interest, equilibrium assignments are particularly important in e.g. spectrum auctions as governments typically want all regions of the country to have coverage. As the bidders’ approximated preferences do not necessarily coincide with their true preferences, the equilibrium concept analyzed in this paper is denoted an approximated Walrasian equilibrium. It is shown that imposing the gross substitutes condition on the approximated preference relations of the bidders is sufficient for the set of approximated Walrasian equilibrium prices to be non-empty. Moreover, the gross substitutes condition also ensures that the set of approximated Walrasian equilibrium prices forms a complete lattice and hence contains a unique minimal element. The auction process is described as an English auction, but as all information is gathered at one point in time, the process can be executed quickly as a one-round auction. The price trajectory will in part be determined by the bidders’ aggregate requirement of the various packages at different prices. It is shown that given any prices of the two types of items, there exists an assignment such that each bidder is assigned a package that she demands if and only if the aggregate requirement for any package, at the given prices, is weakly less than the number of available quantities of that package. Making use of this fact for determining when the process should stop raising prices, it is shown that the proposed process always converges to the unique minimal approximated Walrasian equilibrium price vector. Unique minimal equilibrium prices may be of particular importance when the auctioneer is concerned of consumer welfare. A government selling spectrum licenses may be interested in assuring low consumer prices. Selling the licenses for the smallest equilibrium prices may aid in achieving this as the resulting producer costs are relatively low.

The paper is outlined as follows. Section 2 introduces the basic model and some definitions. The approximation procedure is described in Section 3. In Section 4, results concerning the existence of approximated Walrasian equilibrium are presented. Section 5 contains a description of the auction process and related results. Section 6 concludes the paper. All proofs are collected in the appendix.

2 The model

A finite number of bidders, collected in the set \( N = \{1, 2, \ldots, n\} \), participate in the auction. A seller wishes to auction two types of indivisible items, called \( a \) and \( b \),\(^4\) of which there

\(^4\)To simplify the notation we let \( a \) and \( b \) denote both the item and a set containing the item, i.e., \( a \equiv \{a\} \) and \( b \equiv \{b\} \).
Formally, let $\mu : N \rightarrow I$ be an assignment such that $\#N_a \leq q_a$ and $\#N_b \leq q_b$, where $N_a = \{i \in N \mid \mu(i) \in \{a, ab\}\}$ and $N_b = \{i \in N \mid \mu(i) \in \{b, ab\}\}$, and where $\mu(i)$ denotes the assignment of bidder $i \in N$.

### 3 Approximation

In order to approximate the true preference relation, $R_i$, of any bidder $i \in N$, the bidder makes two reports. The first report, denoted $v$, consists of one price $v_j \in \mathbb{R}$ for each package $j \in \{a, b, ab\}$. Recalling that the price of the null-item is normalized to 0, these reported prices should be such that the bidder is indifferent between the consumption bundles $(0, 0)$, $(a, v_a)$, $(b, v_b)$, and $(ab, v_{ab})$. The second report, $z$, consists of some other prices $z_j < v_j$, which makes the bidder indifferent between the consumption bundles $(a, z_a)$, $(b, z_b)$, and $(ab, z_{ab})$. It should be emphasized that any price reported for $ab$ need not necessarily equal the sum of the prices reported for the individual items. It can be noted that the assumptions on $R_i$ guarantee the existence of prices which fulfill the requirements of the reports. Assuming that the bidders report truthfully, the two reports will be used to make linear approximations of all prices which makes the bidder indifferent between any two.
different packages together with those prices. These approximations will be referred to as a bidder’s **approximated indifference curves**.

The approximated indifference curves will be constructed under the restriction that \( p_{ab} = p_a + p_b \). The package \( ab \) will therefore be sold for \( p_{ab} = p_a + p_b \) and no price discrimination is hence allowed. In line with this, four constants are defined based on the two reports: \( \alpha_v = v_{ab} - v_b \), \( \alpha_z = z_{ab} - z_b \), \( \beta_v = v_{ab} - v_a \), and \( \beta_z = z_{ab} - z_a \). A constant \( \alpha_j \), where \( j \in \{v,z\} \), is interpreted as a price for item \( a \), which would make the bidder indifferent between the consumption bundles \((b,j_b)\) and \((ab,\alpha_j + j_b)\). \( \beta_j \) has the corresponding interpretation for a price of item \( b \). In this way, six pairs of prices, \((p_a, p_b)\), are extracted with the help of which the approximated indifference curves between any two packages, except 0, are constructed.

In the following, a number of formal concepts will be introduced. In order to ease the understanding of the approximation procedure, an example will accompany these concepts. The example is depicted in Figures 1 - 4 and is based on that a bidder \( i \) makes the following reports of \( v \) and \( z \):

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>ab</th>
<th>( \alpha_j )</th>
<th>( \beta_j )</th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>10</td>
<td>8</td>
<td>14</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>z</td>
<td>6</td>
<td>5</td>
<td>10</td>
<td>5</td>
<td>4</td>
</tr>
</tbody>
</table>

From the reported prices it follows that \( \alpha_v = 6 \), \( \beta_v = 4 \), \( \alpha_z = 5 \), and \( \beta_z = 4 \). Assuming truthful reports, two pairs of prices \((10,8)\) and \((6,5)\) are obtained such that \((a,p_a)I_i(b,p_b)\) for bidder \( i \). In addition, \((10,4)\) and \((6,4)\) are interpreted as prices for which \((a,p_a)I_i(ab,p_a + p_b)\) and for \((6,8)\) and \((5,5)\) it follows that \((b,p_b)I_i(ab,p_a + p_b)\). These six pairs of prices are shown in Figure 1 and will be the basis for the linear approximation of the bidder’s indifference curves.

In order to construct the approximated indifference curve between the packages \( a \) and \( b \) in general, the two pairs of prices \((v_a, v_b)\) and \((z_a, z_b)\) are used in defining the following linear function:

\[
f_1(p_a) = y_b + (p_a - z_a)\left(\frac{v_b - z_b}{v_a - z_a}\right) \tag{1}
\]

Figure 1

Figure 2
\((v_a, v_b) = (10, 8)\) and \((z_a, z_b) = (6, 5)\) in our example, and \(f_1\) is depicted in Figure 2. Similarly, the pairs of prices \((v_a, \beta_v)\) and \((z_a, \beta_z)\) are used to construct the approximated indifference curve between the packages \(a\) and \(ab\), while \((\alpha_v, v_b)\) and \((\alpha_z, z_b)\) are used for \(b\) and \(ab\), in the following way:

\[
f_2(p_a) = \beta_z + (p_a - z_a) \left(\frac{\beta_a - \beta_z}{v_a - z_a}\right) \tag{2}
\]

\[
f_3(p_b) = \alpha_z + (p_b - z_b) \left(\frac{\alpha_v - \alpha_z}{v_b - z_b}\right) \tag{3}
\]

The construction of these three approximated indifference curves for the bidder of our example is displayed in Figure 2. Though not depicted, it should be emphasized that the approximated indifference curves are defined for any \(p_a, p_b \in \mathbb{R}\). Finally, the approximated indifference curves between 0 and any other package \(x\) is given by \(v_x\).

By combining an approximated indifference curve with price monotonicity, prices which make the bidder strictly prefer one consumption bundle over another consumption bundle can be approximated. For example, as a bidder reports that she is indifferent between \((a, v_a)\) and \((b, v_b)\), it follows by price monotonicity that the bidder strictly prefers \((a, p_a)\) to \((b, p_b)\) if \(p_a \leq v_a\) and \(p_b > v_b\) or \(p_a < v_a\) and \(p_b \geq v_b\). Similarly, prices \(p_a\) and \(p_b\) for which the bidder would strictly prefer \((b, p_b)\) to \((a, p_a)\) are found by reversing the inequality signs. By applying this reasoning to any pair of prices \((p_a, p_b)\) for which \(f_1(p_a) = p_b\) is true, all pairs of prices that generate strict preferences between \((a, p_a)\) and \((b, p_b)\) are approximated. Returning to the example, Figure 3 depicts strict preferences between the consumption bundles \((a, p_a)\) and \((b, p_b)\). \((a, p_a)\) is strictly preferred to \((b, p_b)\) for any pair of prices above and to the left of \(f_1\) whereas \((b, p_b)\) is strictly preferred to \((a, p_a)\) for any pair of prices below and to the right of \(f_1\). By applying this reasoning to any two consumption bundles containing different packages, the approximated indifference curves and price monotonicity approximate the true preferences of a bidder. Let \(\succsim_i\) denote the \textit{approximated preference relation} of any bidder \(i \in N\). Furthermore, \(\succ_i\) and \(\sim_i\) are the strict- and indifference relations associated with \(\succsim_i\).

In order for the approximated preference relation of a bidder to be meaningful, it is important that, at any given prices of the items, a consistent ranking of the consumption bundles can be constructed. Proposition 1 ensures that this is the case.
Proposition 1. For any given prices of the items, the approximated preference relation of each bidder $i \in N$ is complete and transitive.

The rational approximated preference relation of the bidder in our example is depicted in Figure 4. Figure 4 also shows the combination of prices for which a certain consumption bundle is uniquely most preferred.

For a bidder whose preferences are quasi-linear in money, her indifference curves are linear. If prices are reported truthfully, the resulting approximated indifference curves will coincide with the true indifference curves of the bidder. The bidder’s approximated- and true preferences will therefore coincide and the quasi-linear preferences are thus contained in the class of preferences corresponding to the approximation procedure described in this section.

4 Existence

Given the approximated preference relations of the bidders, it is of interest to know whether it is always possible to find an equilibrium assignment. A commonly analyzed equilibrium concept is Walrasian equilibrium. However, as the approximated preference relations do not necessarily coincide with the true preferences of the bidders, the equilibrium concept is denoted an approximated Walrasian equilibrium. In order to define this formally, let a price vector be denoted by $p = (p_0, p_a, p_b) \in \mathbb{R}^3$, which contains one price for each type of item. Furthermore, the approximated demand correspondence of a bidder $i \in N$ is defined as $D_i(p) = \{x \in \mathcal{I} | (x, p_x) \succeq_i (y, p_y) \text{ for all } y \in \mathcal{I}\}$ at any $p$. If $x \in D_i(p)$, then package $x$ is said to be demanded by bidder $i \in N$.

Definition 1. The pair $(p, \mu)$ constitutes an approximated Walrasian equilibrium if: (i) $\mu(i) \in D_i(p)$ for all $i \in N$ and (ii) if $\#N_x < q_x$ for some $x \in ab$, then $p_x = r_x$.

Thus, a price vector $p$ and an assignment $\mu$ constitute an approximated Walrasian equilibrium if each bidder is assigned a package which she demands and if a copy of an item remains unassigned, then the price of said item needs to equal the seller’s reservation price for the item.

An approximated Walrasian equilibrium does not always exist. For an excellent example, see Milgrom (2000) and recall that the quasi-linear preferences are a special case of the approximated preferences of this paper. However, requiring substitutability in the bidders’ preferences has been shown to guarantee the existence of equilibrium assignments in the standard model. Kelso and Crawford (1982) required firms’ preferences over workers to comply with the gross substitutes condition to show the existence of a core allocation. This in turn implies that a Walrasian equilibrium exists in Gul and Stacchetti (1999, 2000). Sun and Yang (2006) showed that the more general gross substitutes and complements condition guarantees the existence of competitive equilibrium. Analyzing the simultaneous ascending auction, Milgrom (2000) showed that if objects are mutual substitutes for the bidders, then the objects can be allocated in accordance with a competitive equilibrium. Similarly in
the matching with contracts model, a stable allocation exists if hospitals view contracts as substitutes (Hatfield and Milgrom, 2005).

Following Kelso and Crawford (1982), the gross substitutes condition is defined as:

**Definition 2.** The approximated preference relation, $\succeq_i$, of any bidder $i \in N$, fulfills the gross substitutes condition if for any two price vectors $p' \geq p$ and any $x \in D_i(p)$, there exists $y \in D_i(p')$ such that \{w $\in x \mid p_w = p'_w$\} $\subseteq y$.

The gross substitutes condition implies that a bidder’s demand for an item does not decrease as the prices of any other items are raised. Let $\mathcal{P} = \{p \in \mathbb{R}^3_+ \mid \exists \mu \text{ s.t } \langle p, \mu \rangle \text{ is an approximated Walrasian equilibrium}\}$ be the set of approximated equilibrium prices. Proposition 2 asserts that if the approximated preference relations of each bidder comply with the gross substitutes condition, then there exists an approximated Walrasian equilibrium.

**Proposition 2.** If the gross substitutes condition is fulfilled for the approximated preference relation of each bidder $i \in N$, then the set of approximated equilibrium prices, $\mathcal{P}$, is non-empty.

It turns out that the gross substitutes condition also guarantees that $\mathcal{P}$ forms a complete lattice. For any two price vectors $p', p'' \in \mathbb{R}^3$, let the meet $p' \land p''$ be defined as a vector $s \in \mathbb{R}^3$ with elements $s_j = \min\{p'_j, p''_j\}$. Similarly, let the join $p' \lor p''$ be a vector $h \in \mathbb{R}^3$ with elements $h_j = \max\{p'_j, p''_j\}$. Any $S \subseteq \mathbb{R}^3$ forms a complete lattice if for each $p', p'' \in S$, $s, h \in S$.

**Proposition 3.** If the gross substitutes condition is fulfilled for the approximated preference relation of each bidder $i \in N$, then $\mathcal{P}$ forms a complete lattice.

Proposition 3 implies that $\mathcal{P}$ contains a unique minimal element. Let this unique minimal approximated Walrasian equilibrium price vector be denoted $p_{\text{min}}$.

## 5 Process

The proposed process is described as an English auction and prices will thus never be decreased. However, as each bidder can report $v$ and $z$ at one point in time, the auctioneer can construct the approximated preference relations of each bidder and then use the auction process proposed in this paper to find an approximated Walrasian equilibrium price vector in a one-round fashion. Following Gul and Stacchetti (2000), the process will use the bidders’ requirement of the different packages in order to, at least partly, determine how prices should be increased.

**Definition 3.** The requirement function $K_i : I \times \mathbb{R}^3 \rightarrow \mathbb{N}_0$ for each $i \in N$ is defined by:

$$K_i(x, p) = \min_{y \in D_i(p)} \#(x \cap y).$$
Let $K_N(x, p) = \sum_{i \in N} K_i(x, p)$ be the bidders’ aggregate requirement of any $x \in I$ at some $p$. Proposition 4, below, justifies the interest in the requirement function. Most importantly, it asserts that when, at some $p$, the bidders’ aggregate requirement for each package is weakly less than the number of existing copies of the items contained in the package, it is possible to assign each bidder a package that she demands. Hence, the first condition for an approximated Walrasian equilibrium is fulfilled at $p$. As any bidder’s requirement of the null-object always equals zero, let $q_0 = 0$ and naturally $q_{ab} = q_a + q_b$.

**Proposition 4.** For a given price vector $p$, there exists an assignment $\mu$ such that $\mu(i) \in D_i(p)$ for all bidders $i \in N$ if and only if $K_N(x, p) \leq q_x$ for all $x \in I$.

Hence, if $K_N(x, p) > q_x$ for some package $x \in I$, then there is more demand for the items contained in $x$, at $p$, than the number of available copies of $x$. To determine the net demand for any package at some price vector $p$, in terms of aggregate requirement, the function $g : I \times \mathbb{R}^3 \to \mathbb{Z} : g(x, p) = K_N(x, p) - q_x$ is defined. Packages with most net demand at $p$ are collected in $O(p) = \{x \in I \mid g(x, p) \geq g(y, p) \text{ for all } y \in I\}$.

**Lemma 1.** $O(p)$ has a unique minimal element with respect to cardinality denoted $O_*(p)$.

Lemma 1 is important for describing the process as whenever $O_*(p) \neq 0$ in any step of the process, the prices of the items contained in $O_*(p)$ will be the main focus of the price increase.

A price increase consists of one part determining how much the prices are increased relative to each other and a second part deciding the magnitude. For the first part, $\delta(p) \in \mathbb{R}^3_+$ is introduced, which has elements $\delta_x(p)$ for each $x \in \{0, a, b\}$ and $p$. Let $p^t$ denote the price vector at step $t$ of the process. The magnitude of a price increase at any step $t$ is then given by $\varepsilon(t) = \sup\{e \mid O_*(p^t + e\delta(p^t)) = O_*(p^t)\}$. In Step 2 of the process, prices of the items contained in $O_*(p)$ are raised by equal amounts. However, as the approximated preferences of the bidders are not necessarily quasi-linear, such a price increase may not always be possible. To solve this problem, let $x \neq y$ for $x, y \in ab$, and $l_x(t) = \inf\{\delta_x(p^t) \in \mathbb{R}_+ \mid \delta_0(p^t) = 0, \delta_y(p^t) = 1, \text{ and } \varepsilon(t) > 0\}$ is defined. $l_x(t)$ and $\delta(p)$ are used to determine the relative price increase of the items.

**Process 1.** Set $t = 0$ and let $p^0 = r$

**Step 1:** If $O_*(p^t) = 0$ set $p^t = p^r$ and stop. Otherwise, go to step 2.

**Step 2:** Let $\delta_x(p^t) = 1$ if $x \in O_*(p^t)$ and 0 otherwise.

\[
\text{If } \begin{cases} 
\varepsilon(t) \neq 0, \quad \text{let } p^{t+1} = p^t + \varepsilon(t)\delta(p^t) \text{ and set } t := t + 1 \text{ and go to step 1.} \\
\varepsilon(t) = 0, \quad \text{go to step 3.} 
\end{cases}
\]

**Step 3:** Let $\delta_0 = 0$ and

\[
\text{if } \begin{cases} 
\text{if } a, ab \in O_*(p^t), \text{ then } \delta_a(p^t) = 1 \text{ and } \delta_b(p^t) = l_b(t). \\
b \in O_*(p^t), \text{ then } \delta_a(p^t) = l_a(t) \text{ and } \delta_b(p^t) = 1. 
\end{cases}
\]
Let $p^{t+1} = p^t + \varepsilon(t)\delta(p^t)$ and set $t := t + 1$ and go to step 1.

Assuming that the bidders’ preferences fulfill the gross substitutes condition, Lemma 2 asserts that the auction process does not get stuck at any step $t < T$.

**Lemma 2.** If the gross substitutes condition is fulfilled for the approximated preference relation of each bidder $i \in N$ and $\varepsilon(t) = 0$ in step 2 of process 1, then $\varepsilon(t) > 0$ in step 3 of process 1.

As $O_*(p^T) = 0$, Proposition 4 ensures that the first condition for $p^T$ to yield an approximated Walrasian equilibrium is fulfilled. Assuming that each bidder’s approximated preference relation complies with the gross substitutes condition, Theorem 1 states that the process always converges to the unique minimal approximated Walrasian equilibrium price vector.

**Theorem 1.** If the gross substitutes condition is fulfilled for the approximated preference relation of each bidder $i \in N$, then Process 1 always terminates at $p^T = p^{min}$.

### 6 Concluding remarks

This paper has provided a procedure for approximating a bidder’s preferences over two types of items when complementarity between the two may exist. A one-round auction is proposed which is shown to always converge to the unique minimal approximated Walrasian equilibrium price vector. The auction process is efficient with respect to the approximated preferences of the bidders. It would therefore be of interest to evaluate the performance of the auction procedure in relation to the bidders’ true preferences. Another more complicated question is whether a perhaps similar approximation procedure can be applied to a more general setting, where bidders are interested in more than two items. Finally, the approximation procedure described in this paper assumes that bidders report truthfully and the auction process is not strategy-proof. Finding a strategy-proof way of conducting a one-round auction, when bidders preferences are not necessarily quasi-linear, would be of great interest and importance.

### 7 Appendix A: Proofs Related to the Approximation

For proving Proposition 1, completeness of $\succeq_i$ for any $i \in N$ will be shown in Lemma 3. Then Lemma 4, which is of technical nature, will be proven to aid in the proof of the transitivity of $\succeq_i$. Transitivity of $\succeq_i$ will be shown in Lemma 5.

Let the consumption set of a bidder be $Z = \mathcal{I} \times \mathbb{R}_+$ and any consumption bundle is a pair $(x, p_x) \in Z$. Let $Z(p)$ denote the consumption set at any $p = (p_0, p_a, p_b) \in \mathbb{R}^3$. For any bidder $i \in N$, $\succeq_i$ is complete if for any given $p$ and for all $(x, p_x), (y, p_y) \in Z(p)$, we have that $(x, p_y) \succeq_i (y, p_y)$ or $(y, p_y) \succeq_i (x, p_x)$ (or both). Let $\mathcal{I}_+ = \{a, b, ab\}$.  

---

11
Lemma 3. For any given prices of the items, the approximated preference relation of each bidder \( i \in N \) is complete.

Proof of lemma 3. Fix \( p = (p_0, p_a, p_b) \). Then as any bidder is assumed to be indifferent between two identical consumption bundles, we need to show that any pair of the four distinct consumption bundles available at \( p \) are related by \( \succ_i \). By the requirements on the bids we know that \( (x, v_x) \sim_i (0, 0) \) for any \( x \in \mathbb{I}_+ \). Assume that \( p_x \leq v_x \). Then it follows by price monotonicity that \( (x, p_x) \succ (x, v_x) \sim_i (0, 0) \). By construction, \( f_i(p_j) = p_k \), for \( i = 1, 2, 3 \), are some prices of \( j, k \in \{a, b\} \), which would make the bidder indifferent between any two packages \( x \neq y \) where \( x, y \in \mathbb{I}_+ \). Assume that \( p_j \leq p_j \) for \( i = 1, 2, 3 \), which by price monotonicity implies that \( (x, p_x) \succ (x, p_x') \sim_i (y, p_y') \sim_i (y, p_y) \), where the identity of the two packages depend on the identity of \( i \). By replacing \( \leq \) with \( \geq \) in the arguments above, the same conclusion is derived by symmetry. \( \square \)

While completeness of the approximated preference relations could be established by only considering one indifference curve at a time, transitivity depends on the construction of different indifference curves. Therefore, it is important to know the relationship of the approximated indifference curves. Let \( c_i \) be the intercept, \( m_i \) the slope of \( f_i \) for \( i = 1, 2, 3 \),
\( c_4 = z_b - \frac{\alpha_2}{m_3} \), and \( m_4 = \frac{1}{m_3} \). We start by noting that since \( v_j > z_j \) for \( j \in \{a, b\} \), it is always the case that \( m_1 = \frac{v_b - z_b}{v_a - z_a} > 0 \).

Lemma 4. The linearly approximated indifference curves have the following relationship:

i. If \( m_j \neq m_k \) for some \( j, k = 1, 2, 4 \), then \( m_1 \neq m_2 \neq m_4 \)

ii. If \( m_1 \neq m_2 \neq m_4 \), then there exist unique \( p_a^* \in \mathbb{R} \) and \( p_b^* \in \mathbb{R} \) such that \( f_1(p_a^*) = f_2(p_a^*) = p_b^* \) and \( f_3(p_b^*) = p_a^* \).

iii. If \( m_3 > 0 \) and \( m_1 \neq m_2 \neq m_4 \), then \( l > m_1 > k \) for \( l, k \in \{m_2, m_4\} \subset \mathbb{R}^2 \) where \( l \neq k \).

iv. \( m_j > -1 \) for \( j = 2, 3 \).

v. If \( m_2 > m_1 \), then \( m_2 > m_1 > m_4 > 0 \).

vi. If \( m_1 = m_2 = m_4 \), then \( l \leq c_1 \leq k \) for \( l, k \in \{c_2, c_4\} \subset \mathbb{R}^2 \) where \( l \neq k \).

vii. If \( c_j \neq c_k \) for some \( j, k = 1, 2, 4 \), then \( c_1 \neq c_2 \neq c_4 \)

Proof. i. By symmetry it is enough to consider one case. Let \( m_1 \neq m_4 \) and to derive a contradiction we assume that \( m_2 = m_1 \neq m_4 \), which is equivalent to \( \frac{\beta_v - z_v}{v_a - z_a} = \frac{v_b - z_b}{v_a - z_a} \neq \frac{\beta_v - z_v}{v_a - z_v} \).

Therefore, \( \beta_v - z_v = v_b - z_b \) and \( v_a - z_a \neq \alpha_v - \alpha_z \). By the definition of the four constants \( \beta_v, \alpha_v, \beta_z, \) and \( \alpha_z \) we know that

\[
\beta_v + v_a = \alpha_v + v_b \tag{4}
\]

and

\[
\beta_z + z_a = \alpha_z + z_b \tag{5}
\]
Using equations (4) and (5) to replace $\alpha_v$ and $\alpha_z$ we get that $\beta_v - \beta_z \neq v_b - z_b$, which is a contradiction.

\(iii\). As any $f_i$ is a linear function for $i = 1, 2, 3$ and $m_1 \neq m_2$, there must exist a unique $p_a^*$ where $f_1 = f_2$. $f_1$ and $f_2$ are defined by equation (1) and (2) respectively. This gives:

$$p_a^* = \frac{z_a(v_b - \beta_v) + v_a(\beta_z - z_b)}{v_b - z_b - \beta_v + \beta_z}$$

(6)

Naturally since $m_1 \neq m_2$ we have $v_b - z_b \neq \beta_v - \beta_z$ and $v_b - z_b - \beta_v + \beta_z \neq 0$. Replacing $p_a$ in equation (1) by (6) gives:

$$p_b^* = \frac{v_b\beta_z - z_b\beta_v}{v_b - z_b - \beta_v + \beta_z}$$

(7)

We proceed by showing that $p_a^*$ and $p_b^*$ can be found for $f_1$ and $f_3$ as well. Replacing $p_b$ in (3) by (1) gives:

$$p'_a = \frac{z_a\alpha_v - \alpha_zv_a}{\alpha_v - \alpha_z - v_a + z_a}$$

(8)

As $m_1 \neq m_4$ it is ensured that $\alpha_v - \alpha_z - v_a + z_a \neq 0$. Replacing $p'_a$ in equation (1) by (8) gives:

$$p'_b = \frac{z_b(\alpha_v - v_a) + v_b(z_a - \alpha_z)}{\alpha_v - \alpha_z - v_a + z_a}$$

(9)

By using equation (4) in (8) as well as (5) in (9) we get $p'_a = p_a^*$ and $p'_b = p_b^*$.

\(iv\). First note that if $m_3 > 0$, then $m_4 > 0$. As $m_1 \neq m_2 \neq m_4$ we either have $m_1 > m_3$ or $m_1 < m_3$ for some $j = 2, 4$. By symmetry it is enough to consider one case. Let $m_1 > m_4$, then $m_1 = \frac{v_b - z_b}{v_a - z_a} > \frac{v_b - z_b}{\alpha_v - \alpha_z} = m_4 > 0$. As $v_b > z_b$ by construction we have $\alpha_v - \alpha_z > v_a - z_a$. Using equation (4) and (5) to replace $\alpha_v$ and $\alpha_z$ we get $\beta_v - \beta_z > v_b - z_b$ and thus $m_2 = \frac{\beta_v - \beta_z}{v_a - z_a} > m_1 = \frac{v_b - z_b}{v_a - z_a}$.

\(v\). As we have a requirement on the reports that $v_{ab} > z_{ab}$ we get $v_{ab} = v_a + \beta_v = v_b + \alpha_v > z_a + \beta_z = z_b + \alpha_z = z_{ab}$ or $v_a - z_a > \beta_z - \beta_v$ and $v_b - z_b > \alpha_z - \alpha_v$. Therefore, $1 > \frac{\beta_v - \beta_z}{v_a - z_a}$ and $1 > \frac{\alpha_z - \alpha_v}{v_a - z_a}$ or equivalently, $-1 < m_2 = \frac{\beta_v - \beta_z}{v_a - z_a}$ and $-1 < m_3 = \frac{\alpha_z - \alpha_v}{v_a - z_a}$.

\(vi\). Let $m_1 = m_2 = \frac{1}{m_3} = m$ and then either $c_1 \leq l$ or $c_1 \geq l$ for $l = c_2, c_4$. By symmetry it is enough to consider when $c_1 \geq c_2$, which implies $c_1 = z_b - z_a \geq \beta_z - \beta_v * m = c_2$ or $z_b \geq \beta_v$. Using (5) to replace $\beta_v$ gives $z_a \geq \alpha_z$ and thus $c_4 = z_b - \alpha_z * m \geq z_b - z_a * m = c_1$.

\(vii\). If $l \neq c_1$ for $l = c_2, c_4$, then by symmetry it is enough to consider one case: Let $c_2 \neq c_1$, which implies $z_a \neq \alpha_z$. Using (5) to replace $\alpha_z$ gives $\beta_z \neq z_b$ and hence $c_4 \neq c_1$. By point \(vi\). of this lemma we must have $c_2 \neq c_1 \neq c_4$. If $c_2 \neq c_4$, then by point \(vi\). of this lemma we have $l \geq c_1 \geq k$ with at least one weak inequality being a strict inequality and we can use the same argument as before.
Lemma 4. For any given prices of the items, the approximated preference relation of each bidder $i \in N$ is transitive.

Proof. As $(x, p_x) \succ_i (x, p_x)$ at any $p$ for any $(x, p_x) \in Z(p)$ it is assumed that $x \neq y \neq w$. Transitivity in any other case follows by completeness. Fix some $p = (p_0, p_a, p_b)$. We start by considering the case when $x, y, w \in I_i$ and then proceed to where one of $x, y, w$ is equal to the null-item 0. By point i. of Lemma 4 it follows that either $m_1 = m_2 = m_4$ or $m_1 \neq m_2 \neq m_4$. These will have to be treated separately. Assume $m_1 \neq m_2 \neq m_4$ and by point ii. of Lemma 4 there exist $p^*_a$ and $p^*_b$ such that $(a, p^*_a) \succ_i (b, p^*_b) \succ_i (ab, p^*_a + p^*_b)$. Let $x \neq y$ for $x, y \in \{b, ab\}$, then we will show the following:

If for any $i \in N$ $(a, p_a) \succ_i (x, p_x)$ and either (i) $(x, p_x) \succ_i (y, p_y)$ or (ii) $(y, p_y) \succ_i (a, p_a)$ at some $p$, then (i) $(y, p_y) \not\sim (a, p_a)$ or (ii) $(x, p_x) \not\sim (y, p_y)$.

By symmetry, the following arguments apply when $\succ_i$ and $\not\sim_i$ are replaced by $\preceq_i$ and $\not\preceq_i$ respectively. Let $f_X$ be the indifference curve between $a$ and $x$ and $f_Y$ be the indifference curve between $y$ and $a$. Note that $X, Y \in \{1, 2\}$ and $X \neq Y$ as $x \neq y$. Moreover, let $f_X(p_a) = p^X, f_Y(p_a) = p^Y$ and $f_3(p_b) = p^3_b$.

Let $V \neq W$ for $V, W \in \{\succ_i, \sim_i\}$. In order to derive a contradiction, assume that $(a, p_a) \succ_i (x, p_x), (x, p_x)W(y, p_y)$, and $(y, p_y)V (a, p_a)$ for any $i \in N$ at some $p$. By price monotonicity it follows that $p^X \leq p_b \leq p^Y$ and, depending on the identity of the packages, either $p^3_a \geq p_a$ or $p^3_a \leq p_a$, with some weak inequality being a strict inequality.

It will now be shown that $p^*_a \neq p_a$. If $p_a = p^*_a$, then $p^*_b \neq p_b$ since otherwise $(a, p_a) \sim_i (b, p_b) \sim_i (ab, p_a + p_b)$, which contradicts the assumption that bidder $i \in N$ is not indifferent between the three consumption bundles. Combining $p^X \leq p_b \leq p^Y$ with $p^*_b \neq p_b$ we get that either $p^X_b \neq p^*_b$ and/or $p^Y_b \neq p^*_b$. This together with $p_a = p^*_a$ imply that the slopes $m_X = \frac{p^X_b - p^Y_b}{p_a - p_b}$ and/or $m_Y = \frac{p^X_b - p^Y_b}{p_a - p_b}$ would be undefined. This contradicts the requirement on the bids that $v_a > z_a$. Hence, $p_a \neq p^*_a$.

Assume that $p_a > p^*_a$. Symmetric arguments, to the ones presented below, can be used when $p_a < p^*_a$. As $m_1 \neq m_2$ by assumption, it follows that $m_Y = \frac{p^X_b - p^Y_b}{p_a - p_b} > m_X = \frac{p^X_b - p^Y_b}{p_a - p_b}$.

Case 1: $y = b$. Then $m_1 > m_2$ and either $m_3 = \frac{p^X_b - p^Y_b}{p_a - p_b}$ or $m_3 = \frac{p^X_b - p^Y_b}{p_a - p_b}$. By price monotonicity $y = b$ requires that $p^3_a \geq p_a > p^*_a$, which implies that we must have $p^*_b \neq p_b$ as $m_3$ would otherwise be undefined, contradicting that $v_b > z_b$. If $p_b > p^*_b$, then $m_1 = \frac{p^X_b - p^Y_b}{p_a - p_b} > m_4 = \frac{p^X_b - p^Y_b}{p_a - p_b} > 0$, which contradicts point iii. of Lemma 4. If $p^*_b > p_b$, then we must have that $m_1 = \frac{p^X_b - p^Y_b}{p_a - p_b} > 0 > \frac{p^X_b - p^Y_b}{p_a - p_b} = m_4 = \frac{p^X_b - p^Y_b}{p_a - p_b} \geq m_2 = \frac{p^X_b - p^Y_b}{p_a - p_b}$. By point iv. of Lemma 4 $m_3 > -1$ and we have $-1 > m_4 \geq m_2$. This is a contradiction of point iv. of Lemma 4.
Case 2: \( y = ab \). Now \( p_3^0 \leq p_a \) and \( m_2 > m_1 = \frac{p_X^1 - p_X^0}{p_a - p_X^0} > 0 \), which requires \( p_b \geq p_b^X > p_b^* \).

Then it follows by point v. of Lemma 4 that \( m_1 = \frac{p_X^1 - p_X^0}{p_a - p_X^0} > m_4 = \frac{p_b^X - p_b^0}{p_b - p_b^0} > 0 \). This in turn requires \( p_b^0 < p_b \leq p_b^X \) and \( p_b^* < p_a \leq p_a^3 \) with some weak inequality being a strict inequality, which is a contradiction.

Next the case when \( m_1 = m_2 = m_4 = m \) is considered, which implies that we can rewrite \( f_3(p_b) = p_3^3 = c_3 + p_b \ast m_3 \) as \( p_b = -\frac{c_3}{m_3} + \frac{p_3^3}{m_3} \). Note that \( c_4 = -\frac{c_3}{m_3} \) and thus \( p_b = c_4 + p_3^3 \ast m \). Let \( x \neq y \neq w \) for \( x, y, w \in \mathcal{I}_+ \), then the following will be shown:

If \( (x, p_x) \succ_i (y, p_y) \) and \( (y, p_y) \succ_i (w, p_w) \) for any \( i \in N \) at some \( p \), then \( (w, p_w) \npreceq_i (x, p_x) \).

To derive a contradiction assume that \( (x, p_x) \succ_i (y, p_y) \), \( (y, p_y) \succ_i (w, p_w) \), and \( (w, p_w) \npreceq_i (x, p_x) \) for some \( i \in N \) at some \( p \). Note that by price monotonicity we either have: (i) \( f_1(p_a) = p_1^1 \leq p_b \leq p_2^1 = f_2(p_a) \) and \( f_3(p_b) = p_3^3 \leq p_a \) or (ii) \( f_1(p_a) = p_1^1 \geq p_b \geq p_2^1 = f_2(p_a) \) and \( f_3(p_b) = p_3^3 \geq p_a \), with at least one weak inequality being a strict inequality. By symmetry it is enough to consider one case. Assume that the three consumption bundles are related such that \( f_1(p_a) = p_1^1 \leq p_b \leq p_2^1 = f_2(p_a) \) and \( f_3(p_b) = p_3^3 \leq p_a \), with at least one weak inequality being a strict inequality. From this it follows that \( p_1^1 = c_1 \ast m_1 \leq p_b = c_4 + p_3^3 \ast m \leq c_4 + p_a \ast m \) and \( p_1^1 = c_1 \ast m_1 \leq p_2^1 = c_2 + p_a \ast m \). Thus, \( c_1 \leq c_4 \) and \( c_1 \leq c_2 \). However, as at least one of the three previous mentioned weak inequalities is a strict inequality we must have that \( c_j \neq c_k \) for some \( j, k \) where \( j, k \in \{1, 2, 4\} \). Therefore, \( c_1 \neq c_2 = c_4 \) by point viii. of Lemma 4. Hence, \( c_1 < c_4 \) and \( c_1 < c_2 \), which is a contradiction of point vi. of Lemma 4.

Finally, the case when \( x, y, w \in \mathcal{I} \) and where one of \( x, y, \) or \( w \) is equal to the null-item 0 is considered. By the requirements of the reports we know that \( (0, 0) \sim_i (a, v_a) \sim_i (b, v_b) \sim_i (ab, v_{ab}) \) for any \( i \in N \). Let \( x \neq y \) for \( x, y \in ab \) and \( l \neq k \neq w \) for \( l, k, w \in \{0, x, ab\} \), then we will show the following:

1. If \( (x, p_x) \succ_i (0, 0) \) and either (i) \( (y, p_y) \succ_i (x, p_x) \) or (ii) \( (0, 0) \succ_i (y, p_y) \) for any \( i \in N \) at some \( p \), then (i) \( (0, 0) \npreceq_i (y, p_y) \) or (ii) \( (y, p_y) \npreceq_i (x, p_x) \).

2. If \( (l, p_l) \succ_i (k, p_k) \) and \( (k, p_k) \succ_i (w, p_w) \) for any \( i \in N \) at some \( p \), then \( (w, p_w) \npreceq_i (l, p_l) \).

Once again, let \( V \neq W \) for \( V, W \in \{\succ_i, \npreceq_i\} \).

1. To derive a contradiction we assume that \( (x, p_x) \succ_i (0, 0) \), \( (y, p_y)V(x, p_x) \), and \( (0, 0)W(y, p_y) \). Combining we have: \( (y, p_y)V(x, p_x) \succ_i (0, 0) \sim_i (y, v_y)W(y, p_y) \). By price monotonicity we have \( p_y \leq v_y \leq p_y \), with at least one of the weak inequalities being a strict inequality.

2. Note that \( p_{ab} = p_x + p_y \). Let \( f_X \) denote the indifference curve between \( x \) and \( ab \) and let \( m_X \) denote its slope. Moreover, let \( f_X(p_x) = p_X^1 \) for some \( p_x \). Assume that \( (l, p_l) \succ_i (k, p_k) \), \( (k, p_k) \succ_i (w, p_w) \), and \( (w, p_w) \npreceq_i (l, p_l) \) at some \( p \). By price monotonicity we either have: \( p_X^1 \geq v_y \), \( p_x \geq v_x \), and \( p_x + p_y \geq v_{ab} \), or \( p_X^1 \leq v_y, p_x \geq v_x, \) and \( p_x + p_y \leq x_{ab} \), with at least one weak inequality being a strict inequality as \( (w, p_w) \succ_i (l, p_l) \). By symmetry it is enough
to consider one case. So assume the consumption bundles are related such that \( p_y^X \geq p_y \), \( p_x \leq v_x \), and \( p_x + p_y \geq v_{ab} \), with at least one weak inequality being a strict inequality. By the requirements of the bids we know that \( v_{ab} = v_x + \eta \), where \( \eta \) is equal to either \( \alpha_v \) or \( \beta_v \), depending on the identity of \( x \). Hence, \( p_x + p_y \geq v_x + \eta \). Therefore, \( p_y - \eta \geq v_x - p_x \) and \( p_y^X - \eta \geq v_x - p_x \geq 0 \). If \( v_x = p_x \), then \( p_y^X = \eta \) as \( f_X(v_x) = \eta \) by construction. From this it follows that \( p_y = \eta \) as \( 0 = p_y^X - \eta \geq p_y - \eta \geq 0 \). Therefore, \( p_y^X = p_y \) and \( p_x + p_y = v_{ab} \). Since some of the three weak inequalities above must be a strict inequality, it must be that \( p_x < v_x \), which is a contradiction. Hence, \( v_x > p_x \) and as \( f_X(v_x) = \eta \) we must have \( m_X = \frac{\eta - p_y^X}{v_x - p_x} \). Since \( p_y - \eta \geq v_x - p_x \) and \( p_y^X \geq p_y \) by assumption, we have \( m_X \leq -1 \), which is a contradiction.

**Proposition 1.** For any given prices of the items, the approximated preference relation of each bidder \( i \in N \) is complete and transitive.

**Proof.** Lemma 3 and Lemma 5 together imply Proposition 1.

8 **Appendix B: Proofs Related to Existence**

In the following sections, it is assumed that the gross substitutes condition is fulfilled for \( \succ_i \) for any \( i \in N \) and if \( x \subset y \), then \( x \) is a proper subset of \( y \). An item is said to be in excess demand if there are more bidders demanding a package containing the item than the number of copies of the item. Similarly, an item is said to be in under demand if there are less bidders demanding a package containing the item than the existing number of copies of the item.

**Proposition 2.** If the gross substitutes condition is fulfilled for the approximated preference relation of each bidder \( i \in N \), then the set of approximated equilibrium prices, \( \mathcal{P} \), is non-empty.

**Proof.** We start by noting that it is always possible to set \( p_a \), \( p_b \), and thus \( p \), sufficiently high such that it is possible to construct an assignment \( \mu \) where \( \mu(i) \in D_i(p) \) for all \( x \in ab \). Let \( \mathcal{C} = \{ p \in \mathbb{R}^3 \mid \exists \mu \text{ s.t. } \mu(i) \in D_i(p) \text{ for all } i \in N \} \), which we know is non-empty. Moreover, \( \mathcal{P} \subset \mathcal{C} \). To derive a contradiction it is assumed that \( \mathcal{P} = \emptyset \). From this it follows that for each \( p \in \mathcal{C} \) there exists some assignment \( \mu \) associated with \( p \) such that \( \#N_x < q_x \) and \( p_x > r_x \) for at least some \( x \in ab \) and where \( \mu(i) \in D_i(p) \) for all \( i \in N \). Let \( \mu_p \) denote an assignment at some price vector \( p \) and \( \mathcal{A}(p) = \{ \mu \mid \mu(i) \in D_i(p) \text{ for all } i \in N \} \) be the set of assignments such that each bidder is assigned a package she demands at price vector \( p \). Let \( r = (r_0, r_a, r_b) \). As \( p \geq r \), it follows that \( \mathcal{C} \) contains some minimal element. Denote such a minimal element by \( s \). The idea of the proof is to show that if \( \mathcal{P} = \emptyset \), then \( s \) cannot be a minimal element of \( \mathcal{C} \).

If \( p_b = r_b \) for some \( p \in \mathcal{C} \), then \( s_b = r_b \) for some \( s \) and it must be that \( \#N_a < q_a \) and \( s_a > r_a \) for any \( \mu_s \in \mathcal{A}(j) \). By symmetry, the following arguments hold when \( b \) and \( a \) are interchanged. For this part of the proof, price monotonicity and the continuity of the approximated indifference curves will imply that \( s \) cannot be a minimal element of \( \mathcal{C} \). Let
\( p' \leq s \) be such that \( p'_b = s_b = r_b \), and \( r_a \leq p'_a < s_a \). By price monotonicity, the demand for item \( b \) has weakly decreased at \( p' \) as compared to at \( s \). Moreover, as \( p'_b = r_b = s_b \) we know that there does not exist excess demand for item \( b \) at \( p' \). Since \( p' \notin C \), it is required that there exist at least some bidder \( k \in N \) for whom \( \mu_{k'} \notin D_k(p') \) at any \( \mu_{k'} \). Since the demand for item \( a \) has weakly increased at any \( p' \), in comparison to \( s \), it must always be possible to find some \( p' \) and \( \mu_{k'} \) where either \( \#N_a = q_a \), if \( p'_a > r_a \), or \( \#N_a \leq q_a \), if \( p'_a = r_a \), and where \( \mu_{k'}(i) \in D_i(p') \) for all \( i \in N \). Because if there exists excess demand for item \( a \) at any \( p' \leq s \) and under demand at \( s \), then there exist at least two bidders who did not demand any package containing \( a \) at \( s \) and who only demand packages containing \( a \) at \( p' \). Collect these bidders in the set \( F \). By price monotonicity and since the approximated indifference curves are continuous, there must exist some price vector \( p'' \) such that \( p' < p'' < s \) for each bidder \( i \in F \) where the bidder is indifferent between a package containing \( a \) and another package not containing \( a \). As item \( a \) is in under demand at \( s \), there must exist some \( p'' \) where it is possible to assign \( \mu_s(j) \) to each \( j \in N \setminus \{i\} \), and in particular to each \( j \in F \setminus \{i\} \), and \( w \supseteq a \) to some \( i \in F \). Therefore, \( \mu_{k'}(i) \in D_i(p'') \) for all \( i \in N \) and \( p'' \in C \), which contradicts the minimality of \( s \).

Now assume that \( p_x > r_x \) for all \( x \in ab \) and \( p \in C \), which implies that there exists at least some minimal element \( s \in C \) such that \( p' \notin C \) for any \( p' \leq s \) where \( p'_x < s_x \) for some \( x \in ab \). Once again, at \( s \) we know that \( \#N_x < q_x \) for at least some \( x \in ab \) at any \( \mu_s \in A(s) \). Assume that \( \#N_a < q_a \) and \( \#N_b \leq q_b \) for some \( \mu_s \in A(s) \). By symmetry, the following arguments can be used if \( a \) and \( b \) are interchanged. Let \( p' \) be a price vector such that \( r_a < p'_a < s_a \) and \( p'_b = s_b \). As \( p' \notin C \) we know that \( \mu_{k'}(i) \notin D_i(p') \) for some \( i \in N \) and there exists excess demand for item \( a \) and/or \( b \).

Assume that item \( b \) is in excess demand at \( p' \). Since the demand for item \( a \) is weakly lower at \( s \), by price monotonicity, and \( b \) must belong to at least some demanded package at \( s \) for any bidder who demands any package \( w \supseteq b \) at \( p' \) by gross substitutes, it follows that \( b \) must be in excess demand at \( s \) as well. This contradicts that \( s \in C \).

So, it must be that \( a \) is the item in excess demand at \( p' \). If \( \#N_a < q_a \) for all \( \mu_s \in A(s) \), then the same argument as for the case when \( s_b = r_b = p'_b \) can be used to generate a contradiction. Therefore, \( \#N_a < q_a \) for some assignment \( \mu'_s \in A(s) \) and \( \#N_a = q_a \), \( \#N'_b < q_b \) for some other assignment \( \mu''_s \in A(s) \) as \( s \notin P \). If \( \#N_b < q_b \) for all \( \mu_s \in A \), then we can use symmetric arguments to case when \( s_b = r_b = p'_b \) in order to derive a contradiction. It must therefore be that \( \#N_a < q_a \) and \( \#N_b = q_b \) at \( \mu'_s \).

In this part it will be shown that it must be possible to find some \( p' \leq s \) such that \( p' \in C \). More specifically, it will be shown that an assignment \( \mu_{k'} \) can be constructed such that \( \mu_{k'}(i) \in D_i(p') \) for all \( i \in N \). To see this, note that for any bidder \( i \in N \) who only demands one package, the price decrease can always be made sufficiently small such that \( D_i(p') = D_i(s) \). For any bidder \( i \in N \) for whom \( 0, x \in D_i(s) \), where \( x \in \{a, b, ab\} \), then either the gross substitutes condition is violated in the case when \( x = ab \) as \( D_i(p) = 0 \) for any \( p \geq s \) where \( p_x > s_x \) for some \( x \in ab \), or it is possible to make the price decrease sufficiently small such that \( x \in D_i(p') \) for any such bidder. Note that \( \mu_i(s) = x \) at any \( \mu_s \in A(s) \) for any such bidder \( i \in N \) as \( s \in P \) otherwise. Therefore, it is possible to construct \( \mu_{k'} \) such that \( \mu_s(i) = \mu_{k'}(i) = x \) for any bidder \( i \in N \) discussed above. Moreover,
any bidder who is indifferent between $x \in ab$ and $ab$ at $s$ must have $\mu_s(i) = ab$ at any $\mu_s \in A(s)$ as $p \in \mathcal{P}$ otherwise. For any price decrease sufficiently small it follows that $D_i(p') \subseteq D_i(s')$. Hence, it is possible to let $\mu_{p'}(i) \subseteq \mu_s(i)$ for any such bidder $i \in N$. The only bidders left to consider are the ones who are indifferent between $a$ and $b$. Note that some such bidder must exist as $\#N_a < q_a$ and $\#N_b = q_b$ for $\mu'_s$ and $\#N_a = q_a$ and $\#N_b < q_b$ for $\mu'_s$. Collect each such bidder in the set $S$. As $\mu_{p'}(i) \subseteq \mu_s(i)$ for all $i \in N \setminus S$ and $\#N_x < q_x$ for some $x \in ab$ at $s$, it follows that, at $p'$, there are more copies of item $a$ and $b$ to assign to the bidders in $S$ than number of bidders contained in $S$. As each bidder $i \in S$ wishes to be assigned only one item at $S$ and prices can always be lowered sufficiently little such that $D_i(p') \subseteq D_i(s)$ for any $i \in S$, there must exist some $p'$ where $\mu_{p'}(i) \in D_i(p')$ for all $i \in S$.

More specifically, let $f^a_i$ be the approximated indifference curve between item $a$ and $b$ for any bidder $i \in S$ and $m^i_1$ its slope. let $T = \{m^i_1 \mid i \in S\}$ and as any $m^i_1 \in \mathbb{R}_+$, the elements in $T$ can be ordered from smallest to greatest. Let $k = \#\{i \in S \mid \mu'_s(i) = b\}$. As $\#N_a < q_a$ and $\#N_b = q_b$ for $\mu'_s$ and $\#N_a = q_a$ and $\#N_b < q_b$, it must be that $k \geq 1$. Pick the $k$th element from $T$ and denote the corresponding approximated indifference curve by $f^a_i$. As $\mu_i(p') = \mu_i(s)$ for all $i \in N \setminus S$ it follows that $k$ is the number of copies of $b$ which are possible to assign to any bidder $i \in S$ at $p'$. Furthermore, $\#S - k + 1$ is the number of copies of $a$ which can be assigned at $p'$. By lowering prices along $f^a_i$ sufficiently little, it must by price monotonicity be that $(b, p_a) \succ_i (a, p_a)$ for a maximum of $k - 1$ bidders $i \in S$, $(a, p_a) \succ_i (b, p_b)$ for a maximum of $\#S - k$ bidders $i \in S$, and $(a, p_a) \sim_i (b, p_b)$ for at least $1$ bidder $i \in S$. As there are more copies of item $a$ and $b$ to assign to the bidders in $S$ than number of bidders contained in $S$ at $p'$ and no bidder requires $ab$, it is possible to let $\mu_{p'}(i) \in D_i(p')$ for all $i \in S$. Therefore, $\mu_{p'}(i) \in D_i(p')$ for all $i \in N$, which contradicts the minimality of $s$. \hfill \Box

Lemma 6 will be used in the proof of Proposition 3.

**Lemma 6.** For any two price vectors $p$ and $p'$ where $p_x > p'_x$ and $p'_y \geq p_y$ for $x, y \in ab$ and $x \neq y$, if for some $i \in N, x \subseteq w$ for some $w \in D_i(p)$, then $x \subseteq w'$ for all $w' \in D_i(p')$.

**Proof.** Let the price vector $p''$ be defined as $p'' = \max\{p_j, p'_j\}$ for all $j \in \{0, a, b\}$. Since $p''_x = p_x$ we know by gross substitutes that there exists some $w \in D_i(p''(p'))$ such that $x \subseteq w$. By price monotonicity $(w, p'_w) \succ_i (w, p''_w) \succ_i (o, p''_o) \sim_i (o, p'_o)$ for any $o \in I$ for which $x \not\subseteq o$. Therefore, $x \subseteq w'$ for all $w' \in D_i(p')$. \hfill \Box

**Proposition 3.** If the gross substitutes condition is fulfilled for the approximated preference relation of each bidder $i \in N$, then $\mathcal{P}$ forms a complete lattice.

**Proof.** It will first be shown that if $p', p'' \in \mathcal{P}$, then $s \in \mathcal{P}$ and then that $h \in \mathcal{P}$ as well. Combining this with the fact that $\mathcal{P}$ is bounded from below by the seller’s reservation prices and from above by some bidder’s report $v$, we can conclude that $\mathcal{P}$ forms a complete lattice.

By definition $p_0 = 0$ for any $p$, so $p_a$ and $p_b$ are the prices of interest. If $\#N_x < q_x$ for some $x \in ab$ at some $p' \in \mathcal{P}$, then we must have $p_x = r_x$ for all $p \in \mathcal{P}$. Therefore, for any
$p', p'' \in \mathcal{P}$, $s \in \mathcal{P}$. Now let $\langle p', \mu' \rangle$ and $\langle p'', \mu'' \rangle$ be two distinct approximated Walrasian equilibria where $p'$ and $p''$ are such that $p'_a > p''_a > r_a$ and $p'_b > p''_b > r_b$. Hence, $\#N_a = q_a$ and $\#N_b = q_b$ for both $\mu'$ and $\mu''$. Let $\mu_b$ be an assignment associated with the price vector $p$. It will first be shown that $\mu' (i) = \mu'' (i)$ for all $i \in N$ and secondly that it is possible to let $\mu' (i) = \mu'' (i) = \mu_a (i) = \mu_b (i)$ for all $i \in N$. Therefore, $\langle s, \mu_a \rangle$ and $\langle h, \mu_h \rangle$ are two approximated Walrasian equilibria.

If $\mu' (i) = a$ for any $i \in N$, then $a \subseteq \mu'' (i)$ by Lemma 6. In order to derive a contradiction, assume $ab \in D_i (p'')$, which by Lemma 6 implies that $b \subseteq w$ for all $w \in D_i (p')$, which is a contradiction. Hence, $\mu' (i) = a$ implies that $\mu'' (i) = a$. Now assume $\mu'' (i) = a$ and $\mu' (i) \neq a$. Since $\#N_a = q_a$ and $\#N_b = q_b$ under both $\mu'$ and $\mu''$, there has to exist some $j \in N \setminus \{i\}$ such that either $a \subseteq \mu' (j)$ and $a \notin \mu'' (j)$, or $b \subseteq \mu'' (j)$ and $b \notin \mu' (j)$, which we know by Lemma 6 does not exist. Therefore, $\mu'' (i) = a$ implies that $\mu' (i) = a$. If $\mu' (i) = ab$, then $a \subseteq \mu'' (i)$ by Lemma 6, which, by using the same arguments as before, implies that $\mu'' (i) = ab$. By symmetry the above arguments apply for the case when $a$ and $b$, together with the assignments, are interchanged. The previous arguments together imply that if $\mu' (i) = 0$ then $\mu'' (i) = 0$.

Now to the second part. For any $i \in N$ for whom $\mu' (i) = \mu'' (i) = y$ for any $y \in \{0, a, b\}$ we know by price monotonicity that $(y, s_y) \succ_i (x, s_x)$ for any $x \in \{0, a, b\}$. In order to derive a contradiction assume that $(ab, s_a + s_b) \succ_i (y, s_y)$. By gross substitutes $a \subseteq w$ for some $w \in D_i (p'')$ and $b \subseteq w$ for some $w \in D_i (p')$. From Lemma 6 it follows that $ab = D_i (p'') = D_i (p')$, which is a contradiction. Finally, for any $i \in N$ for whom $\mu' (i) = \mu'' (i) = ab$, it follows by price monotonicity that $(ab, s_a + s_b) \succ_i (0, 0), (ab, s_a + s_b) \succ_i (ab, p'_a + p'_b) \succ_i (b, s_b)$, and $(ab, s_a + s_b) \succ_i (ab, p''_a + p''_b) \succ_i (a, p''_a) \sim_i (a, s_a)$. It is therefore possible to let $\mu (i) = ab$. Therefore, $s \in \mathcal{P}$.

Lastly it will be shown that $h \in \mathcal{P}$ as well. For any $i \in N$ for whom $\mu' (i) = \mu'' (i) = y$ for any $y \in \{0, a, b\}$ we know by price monotonicity that $(y, h_y) \succ_i (x, h_x)$ for any $x \in \mathcal{I}$. If $\mu' (i) = \mu'' (i) = ab$, then $a \in w$ and $b \in w'$ for some $w, w' \in D_i (h)$ by gross substitutes. Assume $ab \notin D_i (h)$ and $a, b \in D_i (h)$. However, for any price vector $p$ such that $p_a < h_a$ and $p_b = h_b$ it follows by price monotonicity that for a price decrease sufficiently small, $b \notin D_i (p)$, which contradicts the gross substitutes condition. Thus, $h \in \mathcal{P}$.

9 Appendix C: Proofs Related to the Process

For all of the proofs in this section, the following sets of packages are introduced: Let $C_a = \{a, ab, \{a, ab\}\}$, $C_b = \{b, ab, \{b, ab\}\}$ and $C_{a,b} = \{\{a, b\}, \{a, b, ab\}\}$. The reason for this is that the approximated demand correspondence of any bidder who demands some package $x \neq 0$, at some $p$, is a subset of at least one of $C_a$, $C_b$, and $C_{a,b}$. Therefore, at any price vector $p$, it is possible to collect any bidder who demands at least some package $x \neq 0$ into at least one of the following sets: Let $D_a (p) = \{i \in N \mid D_i (p) \subseteq C_a\}$, $D_b (p) = \{i \in N \mid D_i (p) \subseteq C_b\}$, $D_{a,b} (p) = \{i \in N \mid D_i (p) \subseteq C_{a,b}\}$, and $D_{a,b} (p) = \{i \in N \mid D_i (p) = \{ab\}\}$. These sets will be very useful in many of the proofs in this section.

Proposition 4. For a given price vector $p$, there exists an assignment $\mu$ such that $\mu (i) \in$
$D_i(p)$ for all bidders $i \in N$ if and only if $K_N(x,p) \leq q_x$ for all $x \in I$.

**Proof.** We start by showing the if part of Proposition 4: If there exists an assignment $\mu$ for some price vector $p$ such that $\mu(i) \in D_i(p)$ for all $i \in N$, then $K_N(x,p) \leq q_x$ for all $x \in I$.

We know that $K_N(0,p) \leq q_0$ for all $p$. Note that if $K_i(a,p) = 1$ for some $i \in N$, then $i \in D_a(p)$. Thus, $K_N(a,p) = \#D_a(p)$. Since $\mu(i) \in D_i(p)$ for all $i \in N$, it is implied that $D_a(p) \subseteq N_a$. As $\#N_a \leq q_a$ by assumption, it therefore follows that $K_N(a,p) = \#D_a(p) \leq \#N_a \leq q_a$. $K_N(b,p) \leq q_b$ by symmetrical arguments.

We can also note that $K_N(ab,p) = \#D_a(p) + \#D_b(p) + \#D_{a,b}(p)$ since $K_i(ab,p) = 1$ for any $i \in N$ whenever $D_i(p) \in C_a \cup C_b \cup C_{a,b} \setminus ab$, $K_i(ab,p) = 2$ whenever $D_i(p) = ab$, and $D_a(p) \cap D_b(p) \cap D_{a,b}(p) = D_{ab}(p)$. Since $\mu$ is such that $\mu(i) \in D_i(p)$ for all $i \in N$ by assumption, it follows that $D_a(p) \cup D_b(p) \cup D_{a,b}(p) = N_a \cup N_b$ and $D_{ab}(p) \subseteq N_a \cap N_b$. Therefore, $K_N(ab,p) = \#D_a(p) + \#D_b(p) + \#D_{a,b}(p) \leq \#N_a + \#N_b \leq q_a + q_b = q_{ab}$.

We continue by showing the only if part of Proposition 4: If $K_N(x,p) \leq q_x$ for all $x \in I$ at some $p$, then there exists an assignment $\mu$ such that $\mu(i) \in D_i(p)$ for all $i \in N$.

As $K_N(x,p) \leq q_x$ for all $x \in I$, we know from before that $\#D_a(p) \leq q_a$, $\#D_b(p) \leq q_b$ and $\#D_a(p) + \#D_b(p) + \#D_{a,b}(p) \leq q_a + q_b$. Assume that at some price vector $p$ there does not exist a $\mu$ such that $\mu(i) \in D_i(p)$ for all $i \in N$, which implies that for all assignments there exists at least one bidder $i \in N$ such that $\mu(i) \notin D_i(p)$. Denote this bidder by $k$. Note that we can always let $\mu(k) = 0$ so $k \in D_a(p) \cup D_b(p) \cup D_{a,b}(p)$. Moreover, if $\mu(k) = ab$, then it is possible to remove items in order for $\mu(k) \in D_k(p)$. If there would exist a group of bidders $S \subseteq N$ for which $\mu(i) \notin D_i(p)$ for all $i \in S$, then the following arguments would apply to each bidder $i \in S$ individually.

We will focus our attention on an assignment, denoted $\mu$, for which $\#N_x \leq q_x$ for all $x \in ab$, and where each bidder $j \in N \setminus \{k\}$ is matched to a minimal element, w.r.t cardinality, of her demand correspondence. We will show, by way of contradiction, that it is always possible to construct $\mu$ such that each bidder is assigned something which she demands. As $\mu(k) \neq ab$, and $\mu(j) = ab$ if and only if $j \in D_{ab}(p)$ for all $j \in N \setminus \{k\}$ we know that $D_{ab}(p) \supseteq N_a \cap N_b$.

Obviously, it cannot be that $\#N_x < q_x$ for all $x \in ab$. Let $x \neq y$ for $x, y \in ab$. There are two cases to consider:

Case 1: $\#N_l = q_l$ for all $l \in \{a, b\}$. We cannot have $\mu(k) = 0$ because then $D_a(p) \cup D_b(p) \cup D_{a,b}(p) \supseteq N_a \cup N_b$ and $K_N(ab,p) = \#D_a(p) + \#D_b(p) + \#D_{a,b}(p) > \#N_a + \#N_b = q_a + q_b = q_{ab}$. Therefore, $\mu(k) = x$ and hence $y \leq w$ for all $w \in D_k(p)$, as we otherwise would have $\mu(k) \in D_k(p)$. From this it follows that $k \in D_y$ and as $y \notin \mu(k) \mu$ must either be that $k \in D_{ab}(p) \supseteq N_a \cap N_b$, in which case $K_N(ab,p) = \#D_a(p) + \#D_b(p) + \#D_{a,b}(p) > \#N_a + \#N_b = q_a + q_b = q_{ab}$, or $k \in D_y(p) \setminus D_{ab}(p)$, which implies that there does not exist a bidder $j \in D_{a,b}(p)$ such that $y \leq \mu(j)$. If this was true, it would be possible to switch the assignment between bidder $k$ and bidder $j$ yielding $\mu(i) \in D_i(p)$ for all $i \in N$. As $y \notin \mu(j)$ for all $j \in D_{a,b}(p)$, and $k \in D_y$, it follows that $N_y \subset D_y$, and thus $K_N(y,p) = \#D_y(p) > \#N_y = q_y$, which is a contradiction.
Case 2: \( \#N_x < q_x \) and \( \#N_y = q_y \). Now we can always let \( \mu(i) = x \) and if \( N_x = q_x \) in consequence of this, we are back in case 1. As \( \mu(k) = x \notin D_k(p) \) we know that \( y \in w \) for all \( w \in D_k(p) \), and \( k \in D_y \). As \( \#N_x < q_x \) it is implied that there does not exist a bidder \( j \in D_{a,b}(p) \) such that \( y \in \mu(j) \) because then it would be possible to switch the assignment between bidder \( k \) and bidder \( j \). Therefore, \( N_y \subset D_y \), and \( K_N(y,p) = \#D_y > \#N_y = q_y \).

Lemma 1. \( O(p) \) has a unique minimal element with respect to cardinality denoted \( O_*(p) \).

**Proof.** By the construction of \( O(p) \) we know that \( g(x,p) = g(y,p) \) for all \( x,y \in O(p) \). Since \( \#0 < \#a = \#b < \#ab \), we need to show that \( a,b \in O_*(p) \) can never be true.

We will start by showing that if \( x \subseteq y \) for any \( x,y \in \mathcal{I} \), then \( K_i(x) \leq K_i(y) \) for each \( i \in N \). To derive a contradiction, assume that \( x \subseteq y \) and \( K_i(x) > K_i(y) \) for some \( i \in N \), which is equivalent to

\[
\min_{w \in D_i(p)} \#(x \cap w) > \min_{w \in D_i(p)} \#(y \cap w)
\]

Let \( w_1 \in \arg \min_{w \in D_i(p)} \#(x \cap w) \) and \( w_2 \in \arg \min_{w \in D_i(p)} \#(y \cap w) \). If \( w_1 = w_2 = w \), then \( \#(x \cap w) > \#(y \cap w) \) implies that \( x \not\subseteq y \). If, on the other hand, \( w_1 \neq w_2 \), then it must be that \( \#(x \cap w_2) \geq \#(x \cap w_1) > \#(y \cap w_2) \), which in turn implies that \( x \not\subseteq y \).

We will now show that \( K_i(ab,p) \geq K_i(a,p) + K_i(b,p) \) for each \( i \in N \). Since \( a \subseteq ab \) and \( b \subseteq ab \) it follows, by the above, that \( K_i(ab,p) \geq \max\{K_i(a,p), K_i(b,p)\} \). Assume that \( K_i(ab,p) < K_i(a,p) + K_i(b,p) \) for some \( i \in N \) at some \( p \). As \( K_i(a,p), K_i(b,p) \in \{0,1\} \) we must have that \( K_i(a,p) = K_i(b,p) = 1 \). However, \( K_i(a,p) = K_i(b,p) = 1 \) implies that \( D_i(p) = ab \) and thus that \( K_i(ab,p) = K_i(a,p) + K_i(b,p) \) for each \( i \in N \).

\( K_i(ab,p) \geq K_i(a,p) + K_i(b,p) \) for each \( i \in N \) implies that \( K_N(ab,p) \geq K_N(a,p) + K_N(b,p) \) as well as \( g(ab,p) \geq g(a,p) + g(b,p) \). Since \( g(0,p) = 0 \) for all \( p \) we have that if \( O_*(p) = 0 \), then \( g(x,p) \leq 0 \) for all \( x \in \mathcal{I} \). So, if \( a,b \in O_*(p) \), then \( g(a,p) = g(b,p) = s \) for some \( s > 0 \) and \( g(ab,p) \geq 2s \) by the arguments above. This implies that \( O(p) = O_*(p) = ab \), which is a contradiction.

Lemma 2. If \( \varepsilon(t) = 0 \) in step 2 of process 1, then \( \varepsilon(t) > 0 \) in step 3 of process 1.

**Proof.** By construction of Process 1, we know that \( 0 = O_*(p^t) \) if and only if \( t = T \). So assume that \( t < T, O_*(p^t) = x \) for some \( x \in \mathcal{I} \setminus 0 \) and that \( \varepsilon(p^t) = 0 \) in step 2. It will be shown that at any \( p^t \) there always exist some \( e > 0 \) and \( \delta(p^t) \) such that \( O_*(p^t + e \delta(p^t)) = O_*(p^t) \), and hence \( \varepsilon(p^t) > 0 \).

If \( x = O_*(p^t) \in ab \), then by gross substitutes and price monotonicity it must be that by only raising the price of item \( y \), the demand for \( x \) weakly increased and the demand for the other packages contained in \( \mathcal{I} \setminus 0 \) are weakly decreased. As a consequence, the aggregate requirement of \( x \) weakly increases as well. Therefore, if \( \delta_0(p^t) = 0, \delta_x(p^t) = 1, \) and \( \delta_y(p^t) = \infty, \) then \( O_*(p^t + e \delta(p^t)) = O_*(p^t) \) for some \( e > 0 \) sufficiently small in step 3 of the process and there exists \( \varepsilon(t) > 0 \).

Assume \( O_*(p^t) = ab \). The idea of this part of the proof is to construct a particular price vector \( p^t \geq p^t \) and to show that the requirement for \( ab = O_*(p^t) \) is greater than for
any other package at \( p' \). To simplify notation, let \( S = D_{a,b}(p') = \{ i \in N \mid D_i(p) \in C_{a,b} \} \). Furthermore, let \( q^S_a(p) = q_a - K_{N,S}(x,p) \) for any \( x \in ab \) at some \( p \). Let \( p' \) be a price vector such that \( p'_x > p'_x \) for at least some \( x \in ab \). Note that \( K_i(ab,p') = K_i(a,p') + K_i(b,p') \), for any \( i \in N \setminus S \) at any \( p' \) and that for any \( p' \geq p \) it is possible to make the price increase sufficiently small such that \( K_i(ab,p') = K_i(a,p') + K_i(b,p') \) and \( K_i(x,p') \geq K_i(x,p') \) for any \( x \in T \). Therefore, at any such \( p' \) it must be that \( q^S_a(p') \leq q^S_a(p') \) and \( q^S_b(p') \leq q^S_b(p') \).

Moreover, for any \( i \in S \) we have \( K_i(ab,p') = 1, K_i(x,p') = 0 \) for any \( x \in T \setminus ab \). Therefore, 
\[
g(ab,p') = \#S - q^S_a(p') - q^S_b(p') \leq g(ab,p').
\]

The strict inequality follows from \( O_s(p') = ab \) and the weak inequality from the fact that \( q^S_a(p') \leq q^S_a(p') \) for \( x \in ab \) and some \( p' \geq p' \). So, if \( q^S_a(p') < 0 \) for all \( x \in ab \), then 
\[
g(ab,p') = \#S - q^S_a(p') - q^S_b(p') \leq \#S - q^S_a(p') \geq g(x,p') \text{ and } x \in ab.
\]

The weak inequality follows from that \( K_i(x,p') \in \{0,1\} \) for any \( i \in S \). There are two cases two consider:

**Case 1:** \( q^S_a(p') \geq 0 \) and \( q^S_b(p') \geq 0 \). For \( g(ab,p') > 0 \) it has to be that \( \#S = q^S_a(p') + q^S_b(p') \). As before, we have \( 0 < g(ab,p') = \#S - q^S_a(p') - q^S_b(p') \leq g(ab,p') \). Let \( m_i^1 \) be the slope of \( f_i^1 \) for bidder \( i \) such that \( f_i(p'_a) = p'_b \) for all \( i \in S \). Define 
\[
T = \{ m_i^1 \in \mathbb{R} \mid i \in S \} \text{ and let } n = q^S_a(p') + 1. \]

Pick the nth element from \( T \), which we denote \( m_n^1 \). Let \( \delta_0(p') = 0, \delta_0(p') = m_i^1, \) and \( \delta_0(p') = 1 \). By increasing the prices by \( p' = p' + e0(p') \) for some \( e > 0 \) sufficiently small, we must by price monotonicity have that \( (a,p'_a) \succ_i (b,p'_b) \) for a maximum of \( q^S_a(p') \) bidders who belong to \( S \), \( (b,p'_b) \succ_i (a,p'_a) \) for a maximum of \( \#S - q^S_a(p') - 1 \) bidders who belong to \( S \), and \( (a,p'_a) \sim_i (b,p'_b) \) for at least
one bidder \(i \in S\). Therefore,

\[
g(a, p') \leq q_a^S(p') - q_a^S(p')
\]

\[
< #S - q_b^S(p') - q_a^S(p')
\]

\[
\leq #S - q_b^S(p') - q_a^S(p')
\]

\[
= g(ab, p')
\]

The first weak inequality follows from the fact that \(D_i(p') \neq ab\) for any \(i \in S\). The strict inequality follows from \(#S - q_b^S(p') > q_a^S(p')\). Moreover, \(g(b, p') \leq #S - q_a^S(p') - 1 - q_b^S(p') < #S - q_b^S(p') - q_a^S(p') = g(ab, p')\). Hence, \(\alpha(p') = ab\), and there exist \(\varepsilon, \delta(p')\) such that \(\varepsilon(t) > 0\) in step 3 of the process.

Case 2: \(q_a^S(p') \geq 0\) and \(q_b^S(p') < 0\). For \(g(ab, p') > 0\) we need \(g(ab, p') = #S - q_a^S(p') - q_b^S(p') = g(ab, p')\), or \(#S > q_a^S(p')\). Moreover, \(#S > q_a^S(p') \geq q_a^S(p')\) from before. Let \(p'\) be such that \(p'_a = p'_a\) and \(p'_b = p'_b + \gamma\). Then for some \(\gamma > 0\) sufficiently small it must by price monotonicity be that \((a, p'_a) > (b, p'_b)\) for all \(i \in S\). Combining this with \(D_i(p') \neq ab\) for any \(i \in S\) we have, \(g(a, p') = #S - q_a^S(p') < #S - q_a^S(p') - q_b^S(p') = g(ab, p')\), and \(g(b, p') = -q_b^S(p') < #S - q_a^S(p') - q_b^S(p') = g(ab, p')\) since \(#S > q_a^S(p')\). Hence, \(\alpha(p') = ab\), and there exist \(\varepsilon, \delta(p')\) such that \(\varepsilon(t) > 0\) in step 3 of the process. Symmetric arguments can be used if \(q_b^S(p') \geq 0\) and \(q_a^S(p') < 0\). \(\square\)

The proof of Theorem 1 will be decomposed into Lemma 7 and Lemma 9. Lemma 8 will aid in the proof of Lemma 9.

**Lemma 7.** \(p_\text{min} \leq p^T\)

**Proof.** It will be shown that for any \(p \leq p_\text{min}\), for which \(p_x < p_\text{xmin}^\prime\) for some \(x \in ab\), it must be that \(\alpha(p) \neq 0\). As the prices are bounded from below by the seller’s reservation prices it is assumed that \(p_\text{xmin}^\prime > r_x\) for at least some \(x \in ab\). \(p\) is constructed such that \(p_x < p_\text{xmin}^\prime\) for at least some \(x \in ab\). Thus, \(p \notin \mathcal{P}\).

If it is possible to construct some assignment \(\mu\) at price vector \(p\) such that \(\#N_x = q_x\) for any \(x \in ab\), or alternatively \(\#N_x < q_x\) for any \(x \in ab\) for which \(p_x = r_x\), then there must exist \(i \in N\) for whom \(\mu(i) \notin D_i(p)\) as \(p \in \mathcal{P}\) otherwise. \(p \notin \mathcal{P}\) would contradict the minimality of \(p_\text{min}\). By Proposition 4 it follows that \(K_N(x, p) > q_x\) for some package \(x \in \mathcal{I}\) and since \(K_N(0, p) \leq q_0\) for all \(p\) it must be that \(\alpha(p) \neq 0\).

Now assume, in order to derive a contradiction, that \(\mu\) can only be constructed such that \(\#N_x < q_x\) and \(p_x > r_x\) for at least some \(x \in ab\) and that \(\mu(i) \in D_i(p)\) for all \(i \in N\). Then it must be possible to find a price vector \(p'\) \(\leq p\) where an assignment can be constructed such that \(\mu(i) \in D_i(p')\) for all \(i \in N\) and \(\#N_x = q_w\) for any \(x \in ab\) for which \(p'_w > r_w\) and \(\#N_w \leq q_w\) for any \(w \in ab\) for which \(p'_w = r_w\). To see this it can be noted that, by price monotonicity, the demand for any \(w \in ab\) weakly increases as \(p_w\) is decreased. Therefore, by decreasing \(p_w\) to \(p'_w\) it must be possible to find a price vector \(p'\) and an assignment such that either \(p'_x > r_x\) and \(\#N_x = q_x\) or \(p'_x = r_x\) and \(\#N_x \leq q_x\). Furthermore, the demand for the other item \(y \in ab\), for which \(y \neq x\), has weakly decreased. Therefore, \(\#N_y < q_y\) and \(p'_y \geq r_y\). Moreover, \(\mu(i) \in D_i(p')\) for all \(i \in N\) as
there would otherwise exist excess demand for item \( x \), which could be eliminated by raising its price, as there was no excess demand at \( p \). If \( \#N_y < q_y \) and \( p'_y > r_y \), then the price of item \( y \) can be decreased in the same manner. By repeating this process, it must be possible to find some \( p' \leq p \), where an assignment can be constructed, such that \( \mu(i) \in D_i(p') \) for all \( i \in N \) and \( \#N_x = q_x \) for any \( x \in ab \) for which \( p'_x > r_x \) and \( \#N_x \leq q_x \) for any \( x \in ab \) for which \( p'_x = r_x \). This implies however that \( p' \in \mathcal{P} \), contradicting the minimality of \( p^{\min} \). There therefore exists \( i \in N \) such that \( \mu(i) \notin D_i(p) \) and by Proposition 4 it follows that \( K_N(x, p) > q_x \) for some package \( x \in \mathcal{I} \) and since \( K_N(0, p) \leq q_0 \) for all \( p \) it must be that \( O_\ast(p) \neq 0 \). □

For Lemma 8 let \( x \neq y \) for \( x, y \in ab \).

**Lemma 8.** If for any two price vectors \( p \) and \( p' \) where \( p'_x > p_x \), \( p'_y = p_y \), and \( y \subseteq w \) for all \( w \in D_i(p) \) and some \( i \in N \), then \( y \subseteq w \) for all \( w \in D_i(p') \)

**Proof.** By symmetry it is enough to consider when \( x = a \) and \( y = b \). If \( b \in D_i(p) \) for any \( i \in N \), then \( (b, p'_b) \succ_i (k, p'_k) \) for all \( k \in \mathcal{I} \setminus b \) by price monotonicity. If \( ab = D_i(p) \), then \( f_2(p_a) = p'_b > p_b \) by price monotonicity. If, to derive a contradiction, \( a \in D_i(p') \), then \( f_2(p'_a) = p'_b \leq p'_b = p_b \) and \( m_2 = \frac{p_b^2-p'_a}{p'_b-p_a} < 0 \). Let \( p'' \) be a price vector where \( p''_a = p_a \) and \( p''_b = p_b + \gamma \) for some \( \gamma > 0 \), sufficiently small such that \( D_i(p'') = ab \) as well. As \( m_2 < 0 \) there exists a price vector \( k \), for which \( k_a < p'_a \) and \( k_b = p''_b \), where \( f_2(k_a) = k_b < k_b \) and hence \( (a, k_a) \succ_i (ab, k_b) \). Moreover, as \( a \in D_i(p') \) and \( k_a < p'_a \) and \( k_b > p'_b \) we must by price monotonicity have \((a, k_a) \succ_i (x, p_x) \) for \( x \in \{b, 0\} \) as well. Hence, \( D_i(k) = a \), which contradicts the gross substitutes condition since \( b \notin w \) for any \( w \in D_i(l) \).

Now we will show that \( ab = D_i(p) \) implies that \((b, p'_b) \succ_i (0, 0) \). Assume \((0, 0) \succ_i (b, p'_b) \), which by price monotonicity implies that \( p'_b = p_b \geq v_b \). For some price vector \( k \) such that \( k_b = p_b + \gamma \) and \( k_a = p_a \) for some \( \gamma > 0 \) sufficiently small we must have \( D_i(k) = ab \) as well. Let \( k' \) be a price vector where \( k'_b = k_b \) and \( k'_a > k_a \) such that \( k'_a + k'_b > v_{ab} \). From the previous arguments we know that \( a \notin D_i(k') \). Therefore, \( 0 = D_i(k') \). This however, violates the gross substitutes condition since \( b \notin w \) for any \( w \in D_i(k') \). Hence, \((b, k_b) \succ_i (0, 0) \), which concludes the proof.

□

**Lemma 9.** \( p^T \leq p^{\min} \)

**Proof.** To derive a contradiction assume that \( p^t \leq p^{\min} \) for some \( t < T \) but \( p_x^{t+1} > p_x^{\min} \) for some \( x \in ab \). Denote the unique minimal set in excess demand at time \( t \) by \( O_x(p^t) \). We know that there must exist some \( t \) and \( e \in [0, \varepsilon(t)) \) such that \( p'(e) = p^t + e\delta(p^t) \leq p^{\min} \). As \( e < \varepsilon(t) \), it follows that \( O_x(p^t) = O_x(p'(e)) \neq 0 \). Let \( c(p) = \{ x \in ab \mid p_x = p_x^{\min} \} \) for any \( p \). Moreover, let \( c_1 = O_x(p'(e)) \cap c(p'(e)) \) and \( c_2 = O_x(p'(e)) \setminus c_1 \). We start by noting that if \( g(x, p'(e)) > 0 \) for \( x \in ab \), then \( K_N(x, p) = \#D_x(p'(e)) > q_x \). There are two cases to consider:

Case 1: \( c_1 \neq \emptyset \). If \( g(c_1, p'(e)) > 0 \), then either \( c_1 = ab \), in which case \( p^{\min} \notin \mathcal{P} \), or \( c_1 \subset ab \), which implies that \( K_N(c_1, p'(e)) = \#D_{c_1}(p'(e)) > q_{c_1} \). As \( c_1 \subseteq w \) for all \( w \in D_i(p'(e)) \)
for all $i \in D_{c_1}(p'(e))$, it follows by Lemma 8 that $c_1 \subseteq w$ for all $w \in D_i(p_{\text{min}})$ for any such bidder $i$ as well. Therefore, $K_N(c_1, p_{\text{min}}) \geq K_N(c_1, p'(e))$ and hence $g(c_1, p_{\text{min}}) > 0$, which contradicts that $p_{\text{min}} \in \mathcal{P}$.

Now assume that $g(c_1, p'(e)) \leq 0$, which implies that $c_1 \subseteq ab$ and $O_*(p'(e)) = ab$. To simplify let $c_1 = a$ and $c_2 = b$. By symmetry, the following arguments can be used when $a$ and $b$ are interchanged. It will now be shown that $g(a, p_{\text{min}}) > 0$. To see this we start by noting that as $a, b \in D_i(p'(e))$ for all $i \in D_{a,b}(p'(e))$, it follows that $K_i(ab, p'(e)) = 1$ for any such bidder $i \in N$. Therefore, it follows that $g(ab, p'(e)) = \#D_{a,b}(p'(e)) + g(a, p'(e)) + g(b, p'(e))$ and we know that $\#D_{a,b}(p'(e)) \geq 1$ since $O_*(p'(e)) = ab$ and $g(a, p'(e)) \leq 0$. Moreover, as $O_*(p'(e)) = ab$ we know that $\#D_{a,b}(p'(e)) + g(a, p'(e)) + g(b, p'(e)) > g(b, p'(e)) \geq 0$ or $\#D_{a,b}(p'(e)) + g(a, p'(e)) > 0$. By gross substitutes and price monotonicity it must be that $K_i(a, p_{\text{min}}) \geq K_i(a, p'(e))$ for all $i \in N$. In particular, since $a, b \in D_i(p'(e))$ for all $i \in D_{a,b}(p'(e))$, it follows that $K_i(a, p'(e)) = 0$ and by gross substitutes and price monotonicity that $K_i(a, p_{\text{min}}) = 1$ for any such bidder $i \in D_{a,b}(p'(e))$. As $\#D_{a,b}(p'(e)) + g(a, p'(e)) > 0$, it must be that $g(a, p_{\text{min}}) \geq \#D_{a,b}(p'(e)) + g(a, p'(e)) > 0$, which is a contradiction.

Case 2: $c_1 = \emptyset$ and $c_1(p'(e)) \neq \emptyset$. As $c_1 = \emptyset$ and $c_1(p'(e)) \neq \emptyset$ it must be that $e, \delta(p')$ and $\varepsilon(t)$ are generated in step 3 of Process 1. Furthermore, $c_2 = O_*(p'(e)) \neq \emptyset$ and $O_*(p'(e)) \neq ab$ because if $O_*(p'(e)) = ab$, then $c_1 \neq \emptyset$. For simplicity we can let $c_2 = O_*(p'(e)) = a$ but symmetric arguments apply if $c_2 = b$. Let $p''$ be defined as $p''_a = p_{\text{min}}^a = p_a'(e)$ and $p''_b = p_a'(e) + \gamma$ for some $\gamma > 0$ sufficiently small such that $p''_a < p_{\text{min}}^b$. As $e$ was generated in step 3 and $O_*(p') = a = O_*(p'(e))$, we know that $\delta_b = 0$, $\delta_a(p') = 1$, and $\delta_b(p') = l_b(t)$, where $l_b(t) = \min\{\delta_b(p') \in \mathbb{R}_+ \mid \delta_b(p') = 0, \delta_a(p') = 1, \text{and} \varepsilon(t) > 0\}$. More importantly, as $\varepsilon(t) = 0$ in step 2 of Process 1, $O_*(p'(e)) \neq O_*(p'')$.

Note that as $p''_a = p_{\text{min}}^a$ and $p''_b < p_{\text{min}}^b$, we know by Lemma 7 that $O_*(p'') \neq \emptyset$. If $O_*(p''') = b$, then $p'' \notin \mathcal{P}$ as $g(b, p_{\text{min}}) > 0$ by the gross substitutes condition. Thus, $O_*(p'') = ab$, which implies that $g(ab, p'') > g(a, p'')$ or $\#D_{a,b}(p'') + g(a, p'') + g(b, p'') > g(a, p'')$ and hence $\#D_{a,b}(p'') + g(b, p'') > 0$. Since $a, b \in D_i(p'')$ for all $i \in D_{a,b}(p'')$ we know by price monotonicity that $a \notin D_i(p_{\text{min}})$ and by Lemma 8 that $b \in D_i(p_{\text{min}})$ for all $i \in D_{a,b}(p'')$ as well. Furthermore, $K_i(b, p_{\text{min}}) \geq K_i(b, p'')$ for any $i \in N \setminus D_{a,b}(p'')$. Therefore, $g(b, p_{\text{min}}) > 0$, and/or $g(ab, p_{\text{min}}) > 0$, which contradicts that $p_{\text{min}} \in \mathcal{P}$. □

**Theorem 1.** Process 1 always terminates at $p^T = p_{\text{min}}$.

*Proof.* Lemma 7 and Lemma 9 together imply Theorem 1. □
